Abstract

- A binary voxel grid can be represented more efficiently by using a Directed Acyclic Graph(DAG) than Sparse Voxel Octree(SVO)
- Along with efficient encoding of empty regions , DAG allows efficient encoding of identical regions as nodes are allowed to share pointers
- This paper presents a bottom-up algorithm to reduce a SVO to DAG
- The memory consumption of DAG is significantly smaller and it would fit in memory where SVO won't
- DAG requires no decompression and can be traversed easily
- This paper demonstrates this by ray tracing hard and soft shadows , ambient occlusion , and primary rays in extremely high resolution DAG at speed at par or even faster than voxel and triangle GPU ray tracing.

Introduction

- There is increased interest in evaluating secondary rays for effects as reflection, shadows and indirect illumination. Due to the incoherence, a secondary scene representation is required with strict memory budget
- This acceleration structure has to be resident on RAM for efficient access.
- However this is problematic when triangle meshes are augmented with displacement maps as they become infeasibly large to millions of polygons
- Recently Sparse Voxel Octree(SVO) has been used as a secondary scene representation, since they can be efficiently ray traced in real time.
- At high resolution, SVO is still too much memory expensive, therefore it's application has been limited

Introduction

- The data structure **DAG** allows for extremely high resolution enabling us to improve image quality, decrease discretization artifacts, explore high frequency effects like sharp shadows in large scenes.

Figure 1: The EPIC CITADEL scene voxelized to a $128K^3$ resolution and stored as a Sparse Voxel DAG.

Introduction

- The paper presents an efficient technique for reducing the size of SVO by merging common subtrees and transforming to a DAG.
- This can dramatically reduce memory demands in real world scenes and scales even better with increased resolutions.
- This is based on assumption that the original DAG contains a large amount of redundant subtrees
- This paper implements and evaluates algorithms for calculating hard and soft shadows and ambient occlusion by Ray tracing in DAG

Common subtree merging

- work by Webber and Dillencourt [1989], where quadtrees are compressed by merging common subtree
- show a significant decrease (up to 10) in the number of nodes required to represent a 512 512 binary image
- Parker et al. [2003] extends this to three dimensions

Figure 2. Normal quadtree for raster image.

Figure 4. Pointer representation of CSM-quadtree for raster image.

Ambient Occlusion

- screen space ambient occlusion
- precomputation of occlusion into texture [Kontkanen and Laine 2005]
- Ambient occlusion volumes [McGuire 2010]
- Fast Ray-Cast Ambient Occlusion [Laine and Karras 2010]

Reducing a Sparse Voxel Tree to a DAG

Figure 2: Reducing a sparse voxel tree, illustrated using a binary tree, instead of an octree, for clarity.

- The original tree.
- Non-unique leaves are reduced.
- Now, there are non-unique nodes in the level above the leaves. These are reduced, creating non-unique nodes in the level above this.
- The process proceeds until we obtain our final directed acyclic graph.

Terminology

- Consider an N^3 voxel grid as a scene representation where each cell can be represented by a bit : **0** if empty and **1** if it contains geometry
- A sparse voxel octree recursively divided L times gives us a hierarchical representation of an N^3 voxel grid, where $N = 2^L$ and L is called as *max level*.
- A node is implemented with a *childmask*, a bitmask of 8 bits where bit i tells us if bit i contains a geometry, and a pointer to first of non-empty children.
- Child nodes are stored consecutively in memory
- The unique traversal *path*, from root to a specific node in SVO, defines the voxel without storing spatial information explicitly in the node

The sparse voxel DAG

- To Transform an SVO to a DAG we will use a bottom up approach.
- The leaf nodes are defined by uniquely by childmask of 8-bit, so there can be atmost $2^8 = 256$ unique leaf nodes
- Steps of Reduction:
 - ① Merge identical leaves with same bitmask
 - ② Proceed to level above and merge nodes with *Identical childmask* and *Identical pointers*
 - ③ Iteratively perform this step by merging larger and larger subtrees
- The smallest possible DAG is guranteed to be found in L iterations
- This is also applicable for non-uniform octrees and partially reduced DAG's
- This allows us to conveniently build DAGs from SVOs too large to reside in RAM or on disk.

Implementation Details - DAG Construction

- While building a dag of level $L > 10$ we first construct top L-10 levels by triangle/cube intersection in a top down fashion
- For each leaf we construct the subtree till maximum depth
- The subtree is reduced to DAG and then we proceed to next leaf
- After all sub-DAG's get have been constructed, we have top-level SVO with many DAG
- We apply reduction one last time to produce one final DAG
- The result is same as if we processed complete SVO but the memory consumption while construction is considerably low

Implementation Details - Merging Nodes

- We sort the nodes of a level using a *256-bit* (8 child * 32-bit pointer) key and pointer as value
- Identical nodes become adjacent and can be compacted to a single nodes
- We also maintain a table of indirection, for each node we know the pointer to compacted node
- To improve performance we store subtrees of resolution 4^3 of last two rows into a 64-bit integer

Ray Tracing a Sparse Voxel DAG

- The paper implements a GPU-based Raytracer in CUDA that efficiently traverses the scene representation
- The raytracer is primarily used for visibility queries to evaluate hard shadows, soft shadows, and ambient occlusion
- Ambient occlusion is usually approximated by casting a number of rays over the hemisphere and averaging the occlusion of each ray

Evaluation

(a) CRYSPONZA. *Standard game scene.*
(279k triangles)

(b) HAIRBALL. *Highly irregular scene.*
(2.8M triangles)

(c) LUCY. *Laser-scanned model.*
(28M triangles)

(d) SANMIGUEL. *Common GI-benchmark.*
(10.5M triangles)

Figure 3: Scenes used in the experiments.
